# SAT Solvers and Their Strategies

- DPLL-based SAT solvers, their applications and importance
- Strategies of SAT solvers
  - Variable selection strategies
  - Polarity selection strategies
  - Restart strategies
  - Forget strategies
- Choosing SAT solver strategies
- Families of propositional formulae

## Sketch of the Methodology

A methodology of choosing suitable strategies is formulated for an arbitrary given solver. It consists of two steps:

- 1. Systematical solving of a corpus of formulae for all combinations of strategies
- 2. Intelligent choosing of suitable strategies with respect to characteristics of the formula being solved

#### Premise 1

Formulae from the same family share some syntactical properties that can be used for automated formula classification

イロト イヨト イヨト イヨト

#### Premises 2 and 3

- For families of formulae some combinations of strategies show dominantly best results
- For syntactically similar formulae the best combinations of strategies are also similar

イロン イヨン イヨン イヨン

The main message of this work is that intelligent choosing of solvers' strategies, based on the syntax of the input formula, can significantly improve efficiency of a SAT solver.

Important Aspects of the Methodolgy

# Important Aspects of the Methodolgy

Instance-based selection of strategies for SAT solvers Important Aspects of the Methodolgy

# Choice of Method for Classification of Propositional Formulae

Formulae are classified by kNN method using following distance function:

• 
$$d(\mathcal{P}_1, \mathcal{P}_2) \sum_{x \in features} \frac{|f_1(x) - f_2(x)|}{\sqrt{|f_1(x)f_2(x)|} + 1}$$

## Choice of Relevant Features of Propositional Formulae

Formulae are represented by a chosen set of syntactical properties:

- The number of clauses c and variables v in the input formula, and their ratio  $\frac{c}{v}$ ,
- Node degree statistics for variable nodes in variable-clause graph: mean, variation coefficient, minimum, maximum and entropy,
- Fraction of binary clauses, ternary clauses, and Horn clauses,

• ...

- 4 同 6 4 日 6 4 日 6

# Choice of Corpus of Formulae for Training and Evaluation

- Corpus SAT 2002
  - 1964 formulae
  - Around 60 families
- Corpus SAT 2007
  - 906 formulae
  - Around 30 families
- Only 12 shared formulae, and significantly different sets of families

# Description of Methodology

< □ > < □ > < □ >

- 1. Solving formulae for all admissible combinations of strategies
- 2. Determining which combinations of strategies are best on average for different families of formulae
- 3. Making profiles for all the formulae

- 4 同 6 4 日 6 4 日 6

## **Exploitation Phase**

Parametar: k

- 1. Profile building for input formula
- 2. Classification of input formula to some of given families using *k*NN method
- 3. Solving input formula using strategies best for the chosen family

- 4 同 6 4 日 6 4 日 6

# Evaluation of Methodology

# Training Phase

- $\bullet \ \mathrm{ArgoSAT}$  solver was used
- Cutoff time for solving used is 10 minutes
- 60 combinations of strategies
- Clause and variable shuffling
- Number of times that SAT solver was run 235.680
- A cluster computer with 32 processors was used
- Average profile building time 0.39s

(4月) (4日) (4日)

# Evaluation of Automated Formulae Classification (P1)

- Corpus SAT 2002
- The leave one out procedure was used
- The best performance was achieved for k = 1 and the distance d
- Precision: 92.5%
- Average per family precision: 79.2%
- Classification time when the profile is known < 0.1 s

# Analysis of Dominant Combinations of Strategies (P2)

- For each family and each combination we calculated percentage of number of formulae for which that combination is better than the others
- Restriction: at least 10 solved formulae in family
- 15 combinations are not the best for any formula

**Evaluation of Methodology** 

## Analysis of Dominant Combinations of Strategies (P2)

< E

# Similarity of Formulae and Their Best Combinations of Strategies (P3)

Computing similarity correlation:

- For each 2 formulae form the corpus do:
  - a) Calculate distance d between them (syntactical)
  - b) Calculate distance *d<sub>c</sub>* between their best combinations of strategies (semantical)

$$d_c(s_1s_2s_3, t_1t_2t_3) = \sum_{i=1}^3 c(s_i, t_i)$$

- Pearson correlation coefficient is 0.51
- For syntactically similar formulae restart strategy varies the least, and variable selection strategy the most.

# Conclusions

- A syntactical similarity between the formulae of the same family exists, and it can be used for automatic recognition of family the formula belongs to
- There are no unique dominant combinations of strategies, but there exist small sets of such combinations
- Correlation between formula similarity and similarity of their best combinations of strategies is significant
- Intelligent choosing of solvers' strategies, based on the syntax of the input formula, can significantly improve efficiency of a SAT solver
- Improvements achieved by using this methodology are present even a on different corpus
